

# Trials and median sheet

Catch the falling meter stick, read the catch distance in cm, then convert it to milliseconds with the reaction-time strip. Record **at least ten catches** for each condition and take the **median** (the middle value when sorted), not your best single catch. Then test one strategy and compare medians.

Name \_\_\_\_\_ The ONE strategy I tested: \_\_\_\_\_ (for example, focus, warm up)

| TRIAL  | BASELINE CATCH (CM) | BASELINE (MS) | STRATEGY CATCH (CM) | STRATEGY (MS) |
|--------|---------------------|---------------|---------------------|---------------|
| 1      |                     |               |                     |               |
| 2      |                     |               |                     |               |
| 3      |                     |               |                     |               |
| 4      |                     |               |                     |               |
| 5      |                     |               |                     |               |
| 6      |                     |               |                     |               |
| 7      |                     |               |                     |               |
| 8      |                     |               |                     |               |
| 9      |                     |               |                     |               |
| 10     |                     |               |                     |               |
| Median |                     |               |                     |               |

Did the strategy help? Compare your baseline median with your strategy median, and be ready to defend the difference with your data.
